

Industry Analysis: Water Treatment/Sewerage

Idea In Short

Water Treatment/Sewerage converts wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits into outputs that customers can purchase, regulate, finance, or operationalize. The strategic priority is to defend the point in the value chain where scarce capability, customer access, or operating scale creates pricing power. Margin tends to accrue to firms that control network ownership, permits, treatment assets, service territory and process expertise, while standardized activity remains exposed to procurement and substitution. The sector matters because it coordinates collection, primary treatment, biological treatment, advanced treatment, sludge management and discharge or reuse for municipalities, households, industries, commercial facilities and public institutions and its economics are being reshaped by water reuse, nutrient recovery, energy efficiency, climate resilience and stricter discharge requirements. Bargaining power is shifting as technology changes distribution, regulation changes participation and customers gain more ways to compare or replace suppliers.

Water Treatment/Sewerage can be analyzed as a set of linked economic stages rather than as a single market label. The sector coordinates wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits, transforms them through collection, primary treatment, biological treatment, advanced treatment, sludge management and discharge or reuse and reaches customers through sewer networks, treatment plants, reclaimed-water systems and industrial service connections. The strategic question is where value becomes scarce, who controls that scarcity and how technology or regulation can change the answer.

Industry at a glance

Definition and scope. This analysis covers municipal and industrial wastewater collection, treatment, reuse and sewerage services; excludes potable water supply and desalination. The boundary matters because adjacent activities can have different regulation, capital intensity, customer economics and profit pools. Keeping the scope narrow makes the

competitive diagnosis more useful for executives deciding where to invest, partner, automate, or exit.

Economic role. The sector serves municipalities, households, industries, commercial facilities and public institutions. It depends on wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits and reaches demand through sewer networks, treatment plants, reclaimed-water systems and industrial service connections. Its output is valuable when it improves customer economics, reduces risk, increases access, or satisfies a requirement that customers cannot easily meet internally.¹

Indicative metrics. Common revenue patterns include regulated service charges, industrial treatment contracts, connection fees and project concessions. Capital intensity is shaped by sewer networks, treatment plants, pumps, laboratories, monitoring systems and regulatory standards, while labor intensity depends on how much collection, primary treatment, biological treatment, advanced treatment, sludge management and discharge or reuse can be standardized. Regulation intensity is driven by the cost of maintaining compliance, safety, data, licensing, or quality requirements.²

Industry segmentation

The sector separates into distinct operating models because customers buy different forms of value and because the location of scarce resources changes across the value chain. The relevant segments below are useful for comparing economics without treating the whole industry as one market.

1. **Municipal sewerage:** The segment emphasizes a different combination of wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits and customer requirements. Its economics depend on the degree of differentiation, operating scale and customer switching cost.
2. **Industrial wastewater treatment:** The segment emphasizes a different combination of wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits and customer requirements. Its economics depend on the degree of differentiation, operating scale and customer switching cost.
3. **Advanced water reuse:** The segment emphasizes a different combination of

wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits and customer requirements. Its economics depend on the degree of differentiation, operating scale and customer switching cost.

4. Sludge and biosolids management: The segment emphasizes a different combination of wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits and customer requirements. Its economics depend on the degree of differentiation, operating scale and customer switching cost.

5. Decentralized treatment: The segment emphasizes a different combination of wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits and customer requirements. Its economics depend on the degree of differentiation, operating scale and customer switching cost.

Market structure: Porter's Five Forces

The Five Forces analysis shows how network ownership, permits, treatment assets, service territory and process expertise, customer concentration, supplier constraints and substitution interact. The forces are dynamic: technology can lower entry costs, regulation can raise them and consolidation can alter buyer and supplier power simultaneously. The objective is to identify which structural variable is most likely to change the industry's profit pool over the next planning cycle.³

Porter's Five Forces for Water Treatment/Sewerage

Bargaining power of buyers

Customer power in Water Treatment/Sewerage depends on concentration, switching cost, procurement sophistication and the consequences of service failure. Buyers include municipalities, households, industries, commercial facilities and public institutions. Large or professional buyers can pressure price when offers are comparable, but their leverage falls when a provider controls a scarce capability, delivers high reliability, or becomes embedded in service connections, compliance reporting, treatment performance and industrial contracts. In this industry, the key variable is not buyer size alone. It is the buyer's credible outside option and the time required to move to it. Management should track renewal behavior, price realization, concentration and the share of revenue exposed to formal procurement.

Dimension	Observation
Concentration	Large accounts can represent a material share of demand in municipalities
Switching friction	Moving away from an embedded service connections, compliance reporting,

Dimension	Observation
	treatment performance and industrial contracts relationship can impose operational cost
Price transparency	Comparable offers make formal procurement more effective
Outcome sensitivity	Reliability and failure costs can outweigh headline price
Bargaining power of buyers	

Bargaining power of suppliers

Supplier power in Water Treatment/Sewerage comes from the scarcity and substitutability of wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits. Critical suppliers may include people, technology vendors, infrastructure owners, raw-material producers, or regulated service providers. Power rises when qualification is slow, switching interrupts operations, or a supplier controls a bottleneck. It falls when the buyer can standardize specifications, dual-source, redesign the process, or build capability internally. The most exposed firms map supplier concentration to the economic cost of disruption rather than relying on a generic procurement score.

Dimension	Observation
Input scarcity	wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits become leverage points when supply is specialized or constrained
Qualification time	Validation, training, or redesign can delay replacement
Concentration	A narrow supplier base can move margin upstream
Mitigation	Dual sourcing, redesign, integration, or long-term contracts can reduce exposure

Bargaining power of suppliers

Rivalry among existing competitors

Rivalry is shaped by the number and strength of competitors, the degree of product differentiation, fixed costs and the intensity of customer switching. Firms compete across

sewer networks, treatment plants, reclaimed-water systems and industrial service connections and increasingly around network ownership, permits, treatment assets, service territory and process expertise. High fixed costs or excess capacity can push competitors toward discounting. Strong differentiation can redirect rivalry toward quality, service, ecosystem access, or brand. Management should distinguish temporary price competition from a structural decline in willingness to pay.

Dimension	Observation
Market shape	Scale players and focused specialists can compete in different segments
Differentiation	Competition can shift toward network ownership, permits, treatment assets, service territory and process expertise rather than price
Capacity economics	High fixed costs can intensify price competition when demand weakens
Consolidation	M&A can change coverage, purchasing power and investment capacity

Rivalry among existing competitors

Threat of new entrants

Entry into Water Treatment/Sewerage requires more than a product. A credible entrant must assemble sewer networks, treatment plants, pumps, laboratories, monitoring systems and regulatory standards and earn trust in a market where customers already have alternatives. Digital tools can reduce launch costs, but regulation, integration, capital requirements, customer acquisition and operating reliability can preserve incumbent advantages. Entry is most plausible when a new model removes a constraint, targets a neglected segment, or uses a lower-cost distribution mechanism. Incumbents should therefore monitor business-model innovation rather than only direct competitors.

Dimension	Observation
Capital needs	Entry may require investment in sewer networks, treatment plants, pumps, laboratories, monitoring systems and regulatory standards
Credibility	References, approvals, or operating history

Dimension	Observation
	can reduce buyer risk
Technology	Digital delivery can lower the cost of serving a narrow segment
Scale	Incumbents can spread compliance and platform costs across larger revenue bases
Threat of new entrants	

Threat of substitutes

Substitution occurs when customers solve the underlying need through another product, workflow, technology, or internal capability. Relevant alternatives to Water Treatment/Sewerage can emerge from adjacent sectors and from changes in customer behavior. Substitution risk increases when the industry's output becomes standardized and easy to compare. It decreases when the service is embedded in a workflow, carries high failure costs, or depends on trusted infrastructure. Management should track the customer's total process and the economic attractiveness of alternatives, not just conventional competitors.

Dimension	Observation
Internalization	Customers may bring selected activities in-house
Adjacent technology	New tools can alter the preferred workflow
Behavior change	Customers can change channels or consumption patterns
Integration	Deep embedding in service connections, compliance reporting, treatment performance and industrial contracts can make replacement slower
Threat of substitutes	

Value chain and profit pools

The value chain in Water Treatment/Sewerage can be read through five recurring stages: upstream inputs, production or processing, distribution and logistics, the customer interface and enabling infrastructure. The precise activities differ by segment, but the economic logic is consistent. Profit follows control over scarce resources, customer access, or operating density rather than following the number of activities a firm performs.

Upstream inputs

Wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits. The key question is whether supply is abundant, differentiated, or constrained. Qualification and switching costs can transfer bargaining power upstream. In Water Treatment/Sewerage, management should map revenue, contribution margin, working capital and capital employed to this stage instead of treating the industry as a single pool.

Production and processing

Collection, primary treatment, biological treatment, advanced treatment, sludge management and discharge or reuse. Scale matters when it lowers unit cost, improves yield, or increases utilization. Automation matters when it changes the economics of the process rather than merely reducing headcount. In Water Treatment/Sewerage, management should map revenue, contribution margin, working capital and capital employed to this stage instead of treating the industry as a single pool.

Distribution and logistics

Sewer networks, treatment plants, reclaimed-water systems and industrial service connections. Distribution creates advantage when density, reliability, speed, or access lowers the delivered cost of serving customers. In Water Treatment/Sewerage, management should map revenue, contribution margin, working capital and capital employed to this stage instead of treating the industry as a single pool.

Customer interface

Service connections, compliance reporting, treatment performance and industrial contracts. The interface determines who owns the relationship, data, renewal decision and pricing conversation. This can capture more value than the underlying production step. In Water Treatment/Sewerage, management should map revenue, contribution margin, working capital and capital employed to this stage instead of treating the industry as a single pool.

Enabling infrastructure

Sewer networks, treatment plants, pumps, laboratories, monitoring systems and regulatory

standards. Infrastructure can create barriers through standards, licenses, network access, financing, or compliance systems that competitors cannot reproduce quickly. In Water Treatment/Sewerage, management should map revenue, contribution margin, working capital and capital employed to this stage instead of treating the industry as a single pool.

Profit pool

Profit in Water Treatment/Sewerage tends to concentrate where customers face meaningful consequences from failure and where suppliers control scarce capability. That favors businesses with network ownership, permits, treatment assets, service territory and process expertise. Standardized work remains necessary, but it is more exposed to procurement and substitution. Profit pools can shift when water reuse, nutrient recovery, energy efficiency, climate resilience and stricter discharge requirements alter customer willingness to pay or change which capabilities are scarce.⁴

A useful management view separates transaction margin, recurring-service margin and the economic value of customer access. This prevents a common error: treating revenue growth as evidence that the firm controls the attractive part of the value chain. The better question is whether incremental revenue improves price realization, utilization, retention, or return on capital.

Industry economics and business models

Money is made in Water Treatment/Sewerage through a small set of recurring patterns. The sector supports regulated service charges, industrial treatment contracts, connection fees and project concessions. Each pattern allocates risk differently across demand, capacity, input prices and customer behavior. Fixed-price commitments transfer delivery risk to providers, while usage-based pricing shifts volume risk toward customers; recurring contracts can improve predictability but may constrain upside when market conditions move sharply.

Business model design should match the pricing unit to the economic value created. Customers may be buying capacity, access, certainty, expertise, performance, or an outcome. Pricing the wrong unit can increase revenue while adding service complexity and weakening returns.

Cost drivers & scalability

The main cost base includes energy, labor, chemicals, maintenance, sludge handling, capital and compliance. Fixed costs matter when facilities, platforms, specialist teams, or infrastructure must remain available regardless of volume. Variable costs rise with units, transactions, usage, or customer activity. The strategic task is to identify where scale lowers unit cost and where scale instead adds coordination cost.

Scale is valuable when it improves procurement, utilization, data density, network coverage, or service quality. Scope is valuable when one capability can support adjacent products without duplicating the cost base. The flywheel is strongest when better delivery improves trust or engagement, which improves retention and utilization, which then funds further process investment.

Unit economics should connect operating drivers to customer economics. Service models should monitor utilization, productive capacity, quality and retention. Digital models should track acquisition cost, infrastructure cost, engagement and lifetime value where applicable. Asset-heavy models should isolate throughput, yield, downtime and return on capital.

Moats, advantages and strategic levers

Defensibility in Water Treatment/Sewerage can come from cost advantage, differentiation, network effects, switching costs, regulatory access, or data and learning. The strongest sector-specific sources are network ownership, permits, treatment assets, service territory and process expertise. A moat is credible only when it changes customer choice or competitor economics.

Cost advantage can arise from scale, location, process design, utilization, or procurement. Differentiation can come from quality, reliability, brand, specialized knowledge, or workflow integration. Network effects matter when additional users improve the value of the system, while switching costs arise when replacing a provider requires migration, retraining, qualification, redesign, or loss of accumulated data.

Regulatory moats are strongest when compliance requires time, evidence, or operating history. Data moats become meaningful when repeated activity improves prediction, quality, or workflow performance. Management should not label ordinary customer relationships as

moats unless those relationships survive a credible competing offer.

Strategic levers

An entrant or incumbent can pull several levers, but each should be tied to a clear economic hypothesis. The objective is to improve price realization, lower delivered cost, increase retention, or gain control over a scarce input or customer interface.

Customer segment focus

Prioritize customers for whom network ownership, permits, treatment assets, service territory and process expertise has measurable value rather than pursuing the largest theoretical market. The decision should have a measurable leading indicator and an explicit review point. Growth initiatives become expensive when management cannot state which structural variable they are changing.

Product scope

Decide whether to own the full workflow around collection, primary treatment, biological treatment, advanced treatment, sludge management and discharge or reuse or dominate one high-value step. The decision should have a measurable leading indicator and an explicit review point. Growth initiatives become expensive when management cannot state which structural variable they are changing.

Integration versus partnering

Integrate when control of wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits or sewer networks, treatment plants, pumps, laboratories, monitoring systems and regulatory standards changes economics; partner when scale or access is more valuable than ownership. The decision should have a measurable leading indicator and an explicit review point. Growth initiatives become expensive when management cannot state which structural variable they are changing.

Geographic or channel expansion

Expand where customer density and supply conditions improve the economics of sewer

networks, treatment plants, reclaimed-water systems and industrial service connections. The decision should have a measurable leading indicator and an explicit review point. Growth initiatives become expensive when management cannot state which structural variable they are changing.

Ecosystem orchestration

Use standards, platforms, data, or partnerships to become a coordination point for service connections, compliance reporting, treatment performance and industrial contracts. The decision should have a measurable leading indicator and an explicit review point. Growth initiatives become expensive when management cannot state which structural variable they are changing.

Structural risks, regulation and trends

Structural risk in Water Treatment/Sewerage comes from infrastructure failure, compliance penalties, energy costs, extreme weather, source variability and capital needs. Regulatory change can alter who may participate, what evidence is required and which costs are unavoidable. Technology can change the relative economics of labor, capital, distribution, or customer acquisition. Supply shocks can change which side of the market holds bargaining power.⁵

Demand should be modeled through customer budgets, demographics, technology adoption, replacement cycles and regulatory requirements where relevant. Supply should be modeled through capacity additions, consolidation, labor availability, productivity and investment timing. That approach is more useful than relying on a single market forecast.

Three scenarios are useful. In the base case, water reuse, nutrient recovery, energy efficiency, climate resilience and stricter discharge requirements continue at a measured pace and incumbents adapt. In a compression case, price transparency or automation reduces differentiation faster than expected. In a scarcity case, regulation, supply disruption, or concentrated capacity shifts power toward scarce resources. A resilient strategy remains viable across all three.

Strategic playbook

A new entrant should begin with a narrow customer problem where incumbent cost structures or workflows are poorly matched to the need. The wedge should exploit a specific friction in service connections, compliance reporting, treatment performance and industrial contracts or a change created by water reuse, nutrient recovery, energy efficiency, climate resilience and stricter discharge requirements. Build-versus-buy decisions should follow the source of defensibility. Proprietary process knowledge often favors internal development; broad infrastructure often favors partnerships.

Incumbents should defend the part of the business that owns customer trust and recurring economics, then redesign low-differentiation work. Technology investment should lower cycle time, error rates, or delivered cost without weakening the capability customers still value. Portfolio reviews should ask which products improve bargaining power and which simply add revenue.

Executives should establish leading indicators such as win rate, price realization, retention, supplier concentration, utilization, quality, working capital and return on incremental capital. Those measures reveal structural change earlier than revenue growth alone.

Management implications

The operating model in Water Treatment Sewerage creates a second strategic question after the industry structure is understood: which decisions should management make differently because the economics are changing? The answer begins with the allocation of scarce resources. Firms should distinguish capacity that protects service reliability from capacity that merely adds volume and they should distinguish technology that changes unit economics from technology that only changes presentation. This distinction becomes especially important when customers can compare alternatives quickly. A business that responds to price pressure by adding features without reducing delivered cost can increase complexity without improving retention. A business that automates a process without redesigning the surrounding workflow can also preserve the same bottleneck under a different interface.

Management should connect commercial planning to operational constraints. Customer concentration, supplier concentration, utilization, cycle time, quality, working capital and capital intensity should appear in the same review because each can change the bargaining relationship. A customer with high annual spend may have less leverage if the service is

deeply integrated, while a smaller customer may have considerable leverage when switching is immediate. Similarly, a supplier may appear replaceable on paper but become strategically important when qualification, reliability, or geographic constraints limit the practical alternatives. The management team should therefore measure the cost of changing the relationship, not just the number of available suppliers or customers.

Technology investment deserves the same discipline. The first question should be which economic constraint the investment removes. Automation can increase throughput, reduce error, or make a scarce skill less binding. Data can improve forecasting, pricing, or customer retention. Digital distribution can reduce acquisition cost while increasing platform dependence. These effects should be modeled separately. The resulting business case should include the cost of implementation, process redesign, training, cybersecurity and ongoing maintenance rather than treating software or equipment as a one-time purchase.

A useful planning cycle also separates structural changes from cyclical conditions. A temporary shortage can create attractive margins without creating a durable moat. A temporary demand surge can justify overtime without justifying permanent capacity. Conversely, a gradual shift in customer behavior can look small in annual reporting while materially changing the economics of a five-year asset. Management should therefore use leading indicators and scenario ranges, then revisit assumptions when utilization, price realization, retention, or supplier terms move outside the expected band.

The strategic implication is straightforward: protect the constraint that competitors cannot remove quickly and redesign everything that becomes standardized. That approach gives management a practical basis for deciding where to invest, where to partner and where to exit. It also makes the Five Forces analysis operational because each force can be tied to a measurable indicator rather than treated as a static label.

Decision framework

Executives can translate the industry diagnosis into a short sequence of decisions. First, identify the customer segment in which the company has the strongest right to win and define the economic reason for that advantage. Second, map the activities required to deliver the promise and isolate the activities that consume the most capital, labor, management attention, or scarce inputs. Third, test which of those activities customers actually value and which they would replace if a credible alternative appeared. This

sequence prevents management from treating every part of the operating model as equally strategic.

The next step is to quantify the consequences of change. A shift in customer mix can alter utilization, payment terms, service requirements and acquisition cost. A shift in supplier structure can alter quality, lead times, inventory requirements and working capital. A technology change can reduce unit cost while increasing dependence on a platform or specialist vendor. These effects should appear in the same scenario model. Management can then see whether a proposed initiative strengthens the core economics or simply moves cost from one part of the value chain to another.

Portfolio choices should follow the same logic. Businesses with attractive growth but weak bargaining power may require a different strategy from businesses with modest growth and strong control of scarce resources. The former may justify investment in differentiation, distribution, or customer integration. The latter may justify selective capacity expansion or a stronger focus on recurring revenue. The key is to match the investment thesis to the structural position rather than using the same growth playbook across every segment.

The operating dashboard should also include early-warning indicators. Management should watch changes in customer concentration, win rates, renewal behavior, price realization, supplier lead times, capacity utilization, inventory days, quality performance and incremental capital returns. The exact measures differ across segments, but the principle remains constant: leading indicators reveal bargaining-power changes before they appear in reported revenue or profit. A company that sees those changes early can adjust sourcing, pricing, capacity, partnerships, or scope before competitors force the decision.

For Water Treatment Sewerage, the strategic advantage ultimately comes from aligning the commercial model with the operational constraint. If the scarce resource is talent, the business should design around retention, productivity and selective automation. If it is infrastructure, management should optimize utilization and access. If it is customer trust, the company should deepen integration and prove outcomes. If it is distribution, density and service reliability become the central variables. This alignment turns industry analysis into an operating agenda and gives the board a clearer basis for deciding where the next unit of capital should go.

Caselet

Veolia: operating through structural change

History and operating model

Veolia provides a public example of how the economics of Water Treatment/Sewerage can be managed through changing market conditions. Its operating history can be examined through public filings, institutional disclosures and sector evidence. The case is useful because it connects strategic positioning to the practical constraints of wastewater flows, treatment chemicals, energy, infrastructure, skilled labor and permits and sewer networks, treatment plants, pumps, laboratories, monitoring systems and regulatory standards. The organization developed an operating model around a specific customer need and then adjusted its capabilities as technology, regulation, competition, or demand changed.

The operating model shows why scale alone does not guarantee attractive returns. Management must decide which activities should remain proprietary, which can be standardized and which are better sourced from partners. In Water Treatment/Sewerage, those choices determine the balance between fixed cost, flexibility, service quality and customer control. The case also shows the value of sequencing investments:

capabilities that strengthen the customer interface can create the demand visibility needed to justify capacity or technology investments upstream

Industry dynamics

The case reflects the forces shaping Water Treatment/Sewerage. Customers can compare alternatives more easily when offers become standardized, while suppliers gain leverage when specialized inputs are scarce. Regulation can create both cost and protection, depending on whether compliance raises the cost of entry or simply adds overhead to every participant. Technology can reduce the cost of delivery while also lowering entry barriers. The company therefore has to decide whether technology is primarily a cost lever, a differentiation tool, or a new distribution channel.

Competitive pressure also changes with market maturity. Early growth can reward capacity expansion and customer acquisition, but later stages often reward utilization, retention,

procurement discipline and portfolio selection. A company that continues to optimize for volume after the market becomes more competitive can create revenue without creating economic value. The case highlights the need to adjust operating priorities as the profit pool moves.

Value capture

The value-capture question is where Veolia earns returns relative to the broader value chain. The answer depends on control of network ownership, permits, treatment assets, service territory and process expertise, not simply on market share. A firm can hold a large volume position while suppliers, platforms, or customer procurement functions capture much of the economics. Conversely, a focused provider can earn stronger returns when its capability is embedded in the customer's workflow or when replacement would impose meaningful operational risk.

Public evidence should therefore be read through unit economics rather than headline growth. Revenue growth matters when it improves utilization, lowers acquisition cost, strengthens purchasing power, or increases the value of a network or installed base. It matters less when growth requires disproportionate capital, discounts, incentives, or working capital. This distinction is central to evaluating strategic quality in Water Treatment/Sewerage.⁶

Strategic lesson

For executives in Water Treatment/Sewerage, the case supports a practical rule: invest around the constraint that competitors cannot remove quickly. That constraint may be access, trust, regulation, operating density, specialized knowledge, infrastructure, or data. Protect that constraint while using technology to reduce the cost of serving customers. Avoid copying the visible features of a successful incumbent without understanding the economic mechanism underneath them.

The case also shows why portfolio discipline matters. Attractive segments can change as technology lowers costs or regulation alters participation. Management should revisit the source of advantage whenever customer switching becomes easier or a supplier bottleneck becomes less scarce. A durable strategy keeps the organization close to the point where customer value and structural scarcity meet.

Summary

Water Treatment/Sewerage is an economic system built around collection, primary treatment, biological treatment, advanced treatment, sludge management and discharge or reuse and the reliable delivery of value to municipalities, households, industries, commercial facilities and public institutions. Its profit pools favor firms that combine network ownership, permits, treatment assets, service territory and process expertise with disciplined cost management. The principal pressures are infrastructure failure, compliance penalties, energy costs, extreme weather, source variability and capital needs, while structural opportunity comes from water reuse, nutrient recovery, energy efficiency, climate resilience and stricter discharge requirements. Strategic choices should center on segment focus, scope, integration, technology investment and control of the customer interface. Entrants should target a narrow constraint they can remove more efficiently than incumbents. Established firms should protect the relationships and capabilities that create switching friction while redesigning low-differentiation work.
